Poster

MethaneSAT is a recently launched Environmental Defense Fund (EDF) satellite mission designed to monitor methane emissions from over 80% of global oil and gas production, as well as other methane sources, with high precision and fine spatial resolution. The MethaneSAT instrument consists of two push-broom imaging spectrometers: the CH<sub>4</sub> spectrometer (1.598-1.676  $\mu\text{m}$ ) to detect CH<sub>4</sub> and CO<sub>2</sub> absorption near 1.65 and 1.61  $\mu\text{m}$ , and the O<sub>2</sub> spectrometer (1.249-1.305  $\mu\text{m}$ ) to detect O<sub>2</sub> absorption near 1.27  $\mu\text{m}$ .

We present the results of the pre-flight calibration analysis of the MethaneSAT sensors. To reduce risk during the build, a sequence of thermal vacuum campaigns was conducted at component levels culminating in a final flight-system level TVAC during Q4 2023 when the two sensors were fully controlled using flight electronics. We will present the system performance including examples of detector-level residual image, dark current, nonlinearity, gain, and pixel response non-uniformity as well as system-level straylight, radiometric calibration and spectral response function.
