S2S Community Workshop: Toward Minimizing Early Model Biases and Errors in S2S Predictions, June5-7,2024

## Motivation

The correlation coefficient is a popular skill score for the deterministic forecast system.

Measuring non-Linear relationship.

It is much less sensitive to extremes!

Can we still calculate Correlation coefficient for this case??

## NOTES

CORRELATION BETWEEN A DISCRETE AND A CONTINUOUS VARIABLE. POINT-BISERIAL CORRELATION

## BY ROBERT F. TATE

## University of Washington<sup>1</sup>

**1.** Introduction and Summary. A problem of some importance in statistical applications, especially in the field of psychology, is that of finding a measure of association between a discrete random variable X, which takes the values J and 1, and a continuous random variable Y. The ordinary product-moment correlation coefficient  $\rho(X, Y)$  is used for this purpose. It has received the name point-biserial correlation coefficient because of its relation to the biserial correlation coefficient proposed by Karl Pearson for a similar problem. The usual estimator r, based on a random sample  $(X_i, Y_i)$ ,  $i = 1, 2, \dots, n$ , is referred to as the sample point-biserial correlation coefficient.

The psychological value of  $\rho$  (and hence of r) is that it affords a measure of the degree of association between a trait and a measurable characteristic, usually an ability of some kind. For the *i*th individual in a random sample of n individuals,  $X_i$  has the value 1 if the trait is possessed and  $Y_i$  is a measure of the ability in question.

We shall give in Section 2 the appropriate mathematical model, based on normal theory, and the asymptotic distribution of r (Theorem 1), the derivation of which is an elementary application of a well known theorem of Cramér. An important special case of this distribution will be discussed in Section 3, namely that in which X takes the values 0 and 1 with equal probabilities. In this connection a variance-stabilizing transformation will be given (Theorem 2). Numerical work based on this transformation may be carried out with the use of existing tables. In particular, the calculation of confidence limits for  $\rho$  is immediate. Theorem 2 is especially useful in investigating the association between sex and some other characteristic, since animal populations consist of approximately half males and half females. As an illustration of the ease with which calculations may be carried out, a problem is considered in which the trait is male and the characteristic is IQ.

The small-sample distribution of r is quite easily found, although it is difficult to deal with when n is even moderately large, asymptotic methods appearing to be more desirable. This is discussed in Section 4.

### RESUMEN

Este trabajo conciente al examen de uma metodología de la climatología singúrica, la técnica de correlación biserial, que permite investigar, en este cao, la interrelación entre la circulación amortárica y la precipitación. Se analiza el significado de las campos de correlación biserial obtenidos relacionando distintas variables representarios del Dijo de escala sindíptica, particultamente campos de vorticidad, con la precipitación local, con el propósito de ahondar en metodologías que sean simples, eficientes y fáciles de interpretar para ligar la circulación de gran escala con la pequeta secala o local. Se propone uma interpretación basada en las configuraciones de los campos de correlación bierral entre vorticidad en 500 hPa y precipitación, que tiene en cuenta los gradientes de vorticidad anónala con los fectos de contate y curvantar novolcardos, para elcidar posibles de la precipitación. Se utiliza como ajemplo a precipitación dira de los sistemas sindípticos son en gran medida responsables de la preceipitación. Se utiliza como signino la precipitación daria de Córdoba, Argentina, para listeral o resultados. Se puede identificar claramente la posición de los centros anómalos de vorticidad ciónica y anticielónica y de la corriente en chorro en asociación con la ocurrencia de precipitación. El atuilis se hace extensivo para precipitaciones más coposas.

PALABRAS CLAVE: Precipitación, vorticidad, correlación biserial.

#### ABSTRACT

This work concerns the examination of a methodology of synoptic climatology, the biserial correlation technique, which allows studying the relationship between atmospheric circulation and precipitation. The physical meaning of Miserial correlation fields between variables representing synoptic-scale circulation, particularly vorticity fields, and local precipitation is explored. One purpose is to examine this approach used to link the large-scale circulation and the smaller-scale surface environment, which seems to be simple, efficient and easy to interpret. An analysis based on biserial correlation configurations between 500 bPa vorticity and precipitation takes in account anomalous vorticity gradients including curvature and share reflects to describe some mechanisms favoring the occurrence of rainfall. It is shown that anomalies in the curvature of synoptic systems are largely causing precipitation. July recipitation at low similar is used as an example to illustrate the results. The position of the yetoric and anticyclonic anomaly centers and the position of the jet streams in association with precipitation may be nearing the heavier tarihall.

KEY WORDS: Precipitation, vorticity, biserial correlation.

[1] Anthropogenically induced climate change has been hypothesized to add to the risk of extreme river floods because a warmer atmosphere can carry more water. In the case of the central European rivers Elbe and Oder, another possibility that has been considered is a more frequent occurrence of a weather situation of the type "Zugstrasse Vb," where a low-pressure system travels from the Adriatic region northeastward, carrying moist air and bringing orographic rainfall in the mountainous catchment areas (Erzgebirge, Sudeten, and Beskids). Analysis of long, homogeneous records of past floods allows us to test such ideas. M. Mudelsee and co-workers recently presented flood records for the middle parts of the Elbe and Oder, which go continuously back to A.D. 1021 and A.D. 1269, respectively. Here we review the reconstruction and assess the data quality of the records, which are based on combining documentary data from the interval up to 1850 and measurements thereafter. finding both the Elbe and Oder records to provide reliable

Fig. 1. Biserial correlation field between 500 hPa geopotential heights and the daily precipitation ≥0.1 mm at Córdoba (see text), during the austral summer (November to April).

Figure 12. Contour maps of the point-wise biserial correlation coefficient between flood events (Elbe, Oder, winter, summer, classes 1–3) on the one hand and sea level pressure (SLP) or 500 hPa geopotential height (z<sub>600</sub>) time series on the other; time interval, 1658–1990. Significant correlations (section 3.3) are on color scale. A negative (positive) correlation indicates a pressure below (above) the seasonal average at a geographic point during floods. Elbe and Oder catchment areas are located around 50°N, 15°E (Figure 2). See color version of this figure at back of this issue.

## ABSTRACT

Correlation networks identified from financial, genomic, ecological, epidemiological, social, and climatic data are being used to provide useful topological insights into the structure of high-dimensional data. Strong convection over the oceans and the atmospheric moisture transport and flow convergence indicated by atmospheric pressure fields may determine where and when extreme precipitation occurs. Here, the spatiotemporal relationship among sea surface temperature (SST) sea level pressure (SLP) and extreme global precipitation is explored using a

### ABSTRAC

Several skill scores are defined, based on the mean-squar tological standards of reference. Decompositions of these skill scores are formulated, each of which is shown to possess terms involving 1) the coefficient of correlation between the forecasts and observations, 2) a measure of the nonsystematic (i.e., conditional) bias in the forecasts, and 3) a measure of the systematic (i.e., unconditional) bias in the forecasts. Depending on the choice of standard of reference, a particular contain terms relating to the degree of association between the reference forecas These decompositions yield analytical relationships between the respective skill scores ficient, document fundamental deficiencies in the correlation coefficient as a measure of performance, and provide additional insight into basic characteristics of forecasting performance. Samples of operational precipitation probability and minimum temperature forecasts are used to investigate the tw terms in the decompositions. Some implications of the results for the practice of forecast

## 1 Introduction

Skill scores are generally defined as measures of the relative accuracy of forecasts produced by two fore- and correlation coefficients, the relationships between casting systems, one of which is a "reference system" (e.g., see Murphy and Daan 1985). Positive skill (i.e., evidently not been explored. In addition, little if any a favorable difference in accuracy) is usually considered to represent a minimal level of acceptable performance a quantitative appreciation of the deficiencies in the for a set of forecasts. To the extent that the difficulty inherent in forecasting situations is reflected in the level of accuracy of the reference forecasts, skill scores also scribe decompositions of a family of climatological skill take difficulty into account. As a result, they can be used (with appropriate caveats) to compare forecasting tween these measures and the (product moment) corperformance across different locations or time periods. Thus, it is not surprising that skill scores are widely used in evaluating the performance of operational and experimental forecasts (e.g., see Dagostaro et al. 1988; Murphy and Daan 1985).

In the context of forecast verification, correlation curacy and the mean-square-error skill coefficients are measures of the degree of linear asso- ploved in this paper. This section also de  $SS(f, \bar{x}, x)$ 

$$= r_{f_x}^2 - [r_{f_x} - (s_f/s_x)]^2 - [(\bar{f} - \bar{x})/s_x]^2. \quad (12)$$

Forecasts  $f_1, \ldots, f_N$ . Observations  $o_1, \ldots, o_N$ .

MSESS = 
$$1 - \frac{\text{MSE}}{\text{MSE}_{\text{ref}}} = 1 - \frac{\sum_{n=1}^{N} (f_n - o_n)^2}{\sum_{n=1}^{N} (o_n - \overline{o})^2} = 1 - \frac{\text{MSE}}{\hat{\sigma}_o^2}$$

For this reference forecast  $\overline{a}$ , the decomposition of MSESS is

MSESS = AC<sup>2</sup> - 
$$\left(\frac{\hat{\sigma}_f}{\hat{\sigma}_o} - AC\right)^2 - \frac{(\overline{f} - \overline{o})^2}{\hat{\sigma}_o^2}$$

 $MSESS = Frac. explained var. - Cond. bias^2 - Bias^2$ 

BS = REL - RES + UNC

Application: to choose "good models"

----MRI-CGCM3 ----NorESM1-M -NorESM1-ME -MME-23 

## Yajuan et al, 2015

"The models with CCs greater than 0.5 and RMSEs less than 0.37 are selected to pro-duce the "best model ensemble"..."

Each of these components can be decomposed further according to the number of p

$$BS = rac{1}{N}\sum_{k=1}^{K}n_k(\mathbf{f_k}-\mathbf{ar{o}_k})^2 - rac{1}{N}\sum_{k=1}^{K}n_k(\mathbf{ar{o}_k}-\mathbf{ar{o}})^2 + \mathbf{ar{o}}\left(1-\mathbf{ar{o}}
ight)^2$$

conjunction with model verification studies (e.g., see

Arpe et al. 1985; Miyakoda et al. 1972; Sanders 1987).

these two common types of verification measures have

attention has been devoted to the problem of obtaining

correlation coefficient as a measure of forecasting per-

formance. The primary purpose of this paper is to de-

scores that yield insight into (i) the relationships be-

relation coefficient and (ii) the deficiencies in the latter

In section 2, we define the terms "accuracy" and

"skill" and identify the basic measures of these attri-

butes-namely, the mean-square-error m

as a performance measure.

Despite the rather widespread use of both skill scores

$$\sum_{n=1}^{\infty} (o_n - \overline{o})^2$$

$$\sum_{k=1}^{N} (f_{k})$$

## **Concluding Remark**

- **Correlation coefficient can be used for the probabilistic forecast.**
- Point-biserial for naturally dichotomous (yes/No), Biserial for artificial dichotomous (threshold-based category).
- **G** Statistical significance test is an advantage.
- □ No needs for any refence forecast (climatology) to create "skill score".
- □ Simple to communicate to the user community.
- **This score can use with Brier Skill Score to choose the "good model".**
