

Dipole Events Historical Shifts from Dry to Wet

Mark Shafer University of Oklahoma Norman, OK

The Journey into Drought

What is a Dipole?

A pair of equal and opposite electric charges or magnetic poles of opposite sign separated especially by a small distance

An abrupt year-to-year transition from drought to flood (pluvial)

Able to erase multi-year droughts in a matter of months

Based on the work of Jordan and Katy Christian & Jeff Basara, University of Oklahoma.

Christian, J., K. Christian, and J. Basara (2015). Drought and Pluvial Dipole Events within the Great Plains of the United States. *Journal of Applied Meteorology and Climatology*, **54**, 1886-1898.

Defining Dipole Events

Years were categorized as:
Drought: 90% of normal or less
Pluvial: 110% of normal or greater
Normal: 90-110%

Year-to-Year changes from drought to pluvial were identified

Also looked at large inter-annual changes, regardless of phase

- •From very dry to less dry
- •From near-normal to very wet

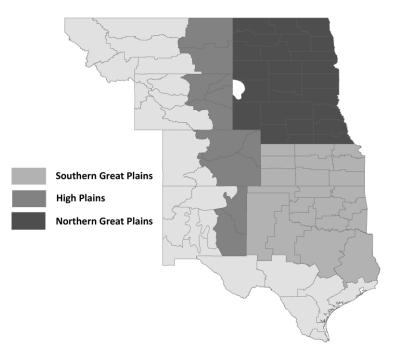

Study Area

3 regions with different climate characteristics -Southern Great Plains (SGP) -Northern Great Plains (NGP) -High Plains (HP)

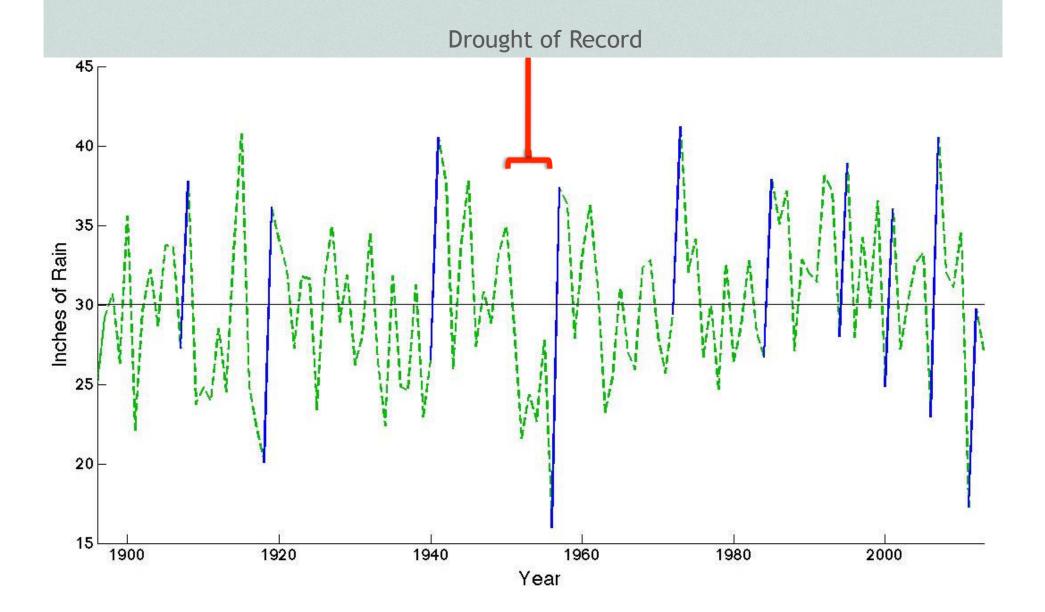

Probability of a significant drought year followed by a pluvial year: -SGP: 25% -NGP: 25% -HP: 16% Climate Divisions within the Southern Great Plains, High Plains, and Northern Great Plains

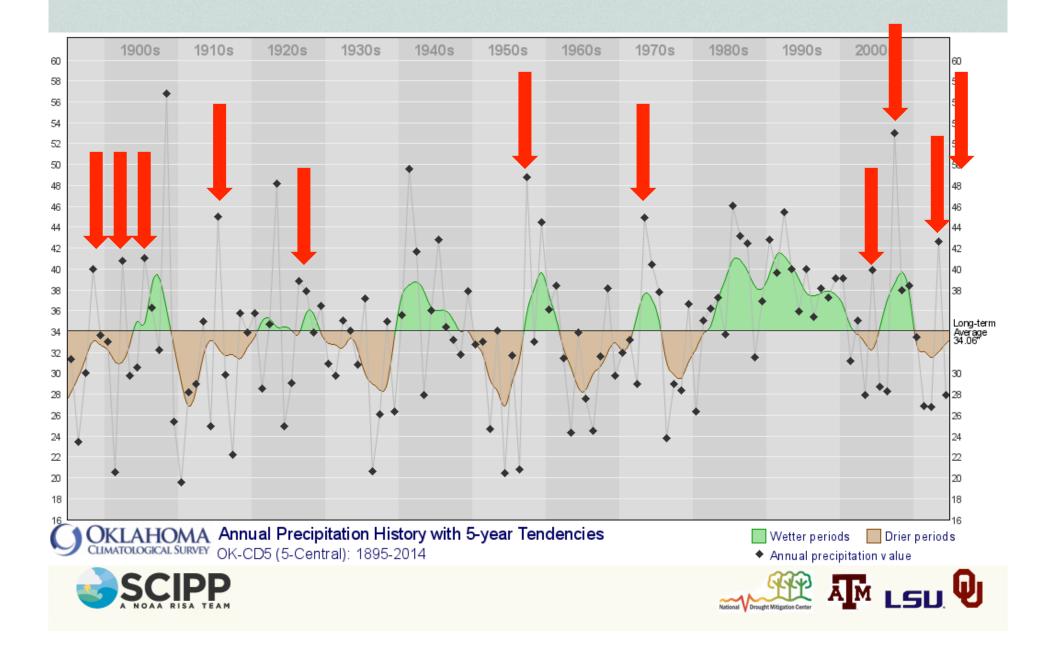

Notable Occurrences in SGP

Historical Dipoles in Central Oklahoma

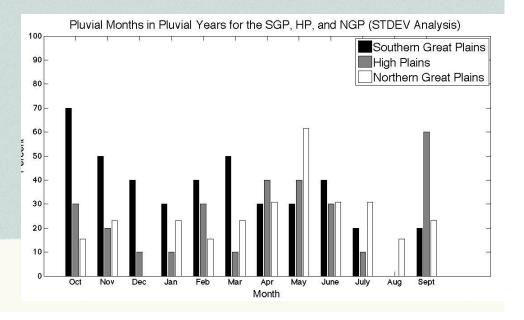

When Does It Happen?

Wettest months of pluvial year varies -Months with 40% or more above normal precipitation

SGP transition most likely fall / late winter

NGP transition most common in spring, especially May

HP transition most common in September with a secondary peak in spring

Becoming more frequent?

In SGP, more common in second half of climate record than first half

Only 3 events 1896-1945 - Average spacing 17 years

7 events 1955-2013 -Average spacing 9 years -3 in last 10 years (if 2015 added)

Oklahoma Climate Division

STDEV Dipole Count for the Oklahoma CDs from 1896-1954 and 1955-2013

No such trends in NGP or HP

Takeaway Messages

Droughts in the Plains often end abruptly

Every area has seen these abrupt transitions

Most likely to occur in Fall or Winter (Southern Plains) or Spring (Northern Plains) but can occur at any time

In the Southern Plains, the flip between dry and wet years appears to be increasingly common

These are just observations from the climate record - the hard part is explaining the causes

Thank You!
